Объяснение и полный каталог
всех изображенных на картах звезд и объектов

ИЗДАТЕЛЬСТВО «НАУКА»
ЛЕНИНГРАДСКОЕ ОТДЕЛЕНИЕ
ЛЕНИНГРАД 1974

Атлас звездного неба состоит из 20 карт, охватывающих все небо от северного до южного полюса. На картах изображены все звезды до 6,5 визуальной величины общим числом свыше 8500, т.е. больше, чем может видеть острый невооруженный глаз. Особо отмечены переменные, двойные и близкие между собой звезды, а также наиболее яркие или интересные звездные скопления и туманности. К атласу приложен полный каталог всех помеченных на картах объектов с указанием их координат, звездной величины, обозначений, созвездий и других данных. В приложенной таблице даны изменения координат вследствие прецессии.

Атлас предназначен для углубленного изучения звездного неба широким кругом специалистов и любителей астрономии, а также работниками школ. Он может служить ключом к нему атласу того же автора (3-е изд., 1969), содержащему звезды до 8,25 величины.

Scan AAW

ОБЪЯСНЕНИЕ К АТЛАСУ

Звездные атласы состоят из собрания карт, на которых в определенных картографических проекциях изображены условными знаками видимые нам на небесной сфере звезды в пределах заданных звездных величин и другие объекты — скопления, туманности и т.д. Проекция выбирается в зависимости от назначения карт, обычно так, чтобы искажения были небольшими и отсчет координат изображенных объектов по координатной сетке был достаточно удобен. Такие карты служат для отождествления звезд на небе при наблюдении невооруженным глазом, в бинокль или в телескоп.

В последние десятилетия в нашей стране были изданы составленные нами атласы: со звездами до 5.5 величины и до 50° южного склонения из четырех карт для общего ознакомления со звездным небом (4-ое издание, 1965 г.) и со звездами до 8.25 величины для всего неба из двадцати карт более специального назначения (3-е издание, 1969 г.). Последний атлас немой, т.е. без границ и названий созвездий и буквенных обозначений звезд. Промежуточного по подробности атласа со всеми звездами, видимыми невооруженным глазом, у нас не издавалось более пятидесяти лет. Поэтому было желательно заполнить этот пробел изданием атласа со звездами до 6.5 величины для всего неба. Такой атлас, имеющий с упомянутым большим атласом одинаковое число и расположение карт, содержащий названия созвездий и обозначения звезд, может служить ему ключом, чему не препятствует некоторое различие эпох равноденствия — 1900.0 в старом большом атласе и 1950.0 в настоящем, а также различие масштабов.

Двадцать карт настоящего атласа охватывают все небо от северного до южного полюса. Соседние карты перекрываются краями на 5° по склонению и на 40 мин. по прямому восхождению. Общее расположение карт пояснено на прилагаемой схеме.

Изображения звезд. Звезды нанесены на карты по экваториальным координатам для равноденствия 1950.0 и условно изображены черными кружками разных диаметров в зависимости от величины звезд с градацией через 0.5 величины согласно следующей схеме:

звезды от	0.76	до	1.25	величины	отнесены к	1.0
	1.26	"	1.75	"	"	1.5
	1.76	"	2.25	"	"	2.0
	2.26	"	2.75	"	"	2.5

	6.26	6.50	"	"	"	6.5

Более точные значения звездных величин дает подробный каталог на стр. 7-42.

На каждой карте под рамкой даны условные знаки: величины звезд, обозначения переменных (var), двойных (dup) и близких между собой (vic) звезд, скоплений (cum), из которых выделены шаровые (g1b) скопления, и туманностей (neb), из которых выделены планетарные (pln) туманности.

Созвездия. Еще в глубокой древности звезды были мысленно объединены в группы, называемые созвездиями. Было выделено 12 созвездий, через которые протекает видимый путь Солнца по звездному небу, называемый эк-

липтикой. Это большой круг, наклоненный к небесному экватору под углом $23^\circ 27'$ и пересекающий его в двух диаметрально противоположных точках — весеннего и осеннего равноденствия. Эклиптика изображена на картах тонкой черной линией.

Схема расположения карт

В остальной части неба, видимой в Европе и странах античного мира, тоже давно было выделено несколько десятков созвездий, названия которых частично связаны с греческими и римскими мифами. При развитии путешествий в южные страны были выделены новые созвездия на южном небе, названные в честь диких животных, птиц и рыб (Хамелеон, Тукан, Золотая Рыба и пр.) или новых научных приборов (Микроскоп, Воздушный Насос и пр.). Обширное созвездие Корабля Аргонатов было впоследствии разделено на четыре части (Киль, Корма, Компас и Паруса). Созвездия разграничивались кривыми

линиями, приблизительно оконтуривавшими фантастические фигуры, изображавшие объекты, по которым названы созвездия. Хотя такое деление неба на созвездия не имеет научного значения, но укоренившийся обычай оказался достаточно удобным для ориентирования среди более ярких звезд и применяется доныне.

Однако в 1925 г. Международный астрономический союз решил упорядочить число, названия и границы созвездий. Было установлено 88 созвездий, перечисленных в табл.1 с их русскими и латинскими именами, а также принятые трехбуквенные сокращения. Границы созвездий были проведены по дугам кругов склонений и суточных параллелей так, чтобы все ранее названные звезды, включая переменные, оставались в пределах прежних созвездий. Поскольку вследствие прецессии координатная сетка смещается относительно звезд, пришлось взять положения упомянутых кругов для некоторой избранной эпохи равноденствия, именно 1875.0 г., для которой имелись подробные звездные карты, в частности южного неба. С тех пор координатная сетка сместилась относительно звезд, с которыми должны быть скреплены границы. Поэтому на наших картах, составленных для равноденствия 1950.0 г., границы созвездий имеют небольшой перекосяк относительно координатной сетки. Во избежание загромождения карт длинными надписями названий созвездий, эти надписи даны на них сокращенные латинские.

Обозначения звезд. В 1603 г. германский астроном И.Байер присвоил звездам в каждом созвездии греческие буквы приблизительно в порядке убывания блеска начиная с α - как правило, с наиболее яркой звезды в созвездии. Когда не хватило греческого алфавита, обозначения были продолжены латинскими строчными буквами за исключением прописной А для лучшего отличия от греческой α . Кроме таких буквенных обозначений звезды имеют также номера, взятые из каталога Флемстида 1725 г., идущие в порядке возрастающих прямых восхождений. Наконец некоторые, обычно более яркие, звезды имеют еще и собственные имена греческого, латинского или арабского происхождения, наиболее употребительные из которых приведены в табл.2.

Таким образом, звезды обозначаются буквой или номером, или тем и другим вместе с названием созвездия в родительном падеже, обычно сокращенным латинским. Так, например, самая яркая звезда всего неба есть Сириус = α Большого Пса = $\theta\alpha$ Canis Majoris = α CMa, или звезда δ Лебеда = δ Cygni = δ Cyg и т.д. Огромное большинство звезд вообще не имеет таких названий, они обозначаются экваториальными координатами с обязательным указанием эпохи равноденствия, часто с прибавлением звездной величины.

На наших картах, во избежание загромождения надписями и потери наглядности, проставлены лишь буквенные обозначения звезд, все остальное содержится в каталоге на стр. 7-42. Когда несколько близлежащих звезд имеет единую букву, но с разными числовыми индексами, буква на карте стоит один раз посреди группы таких звезд, а индексы расставлены у соответствующих звезд. Границы созвездий и все надписи даны на картах красным цветом, который при слабом искусственном освещении становится мало заметным, благодаря чему лучше выделяются изображения звезд.

Каталог звезд. Полный список всех звезд, помеченных на картах, приведен на стр. 7-42. Каталог в порядке столбцов содержит следующие данные:

прямое восхождение α и склонение δ звезды для равноденствия 1950.0, mag - визуальная величина, var означает переменность блеска, sp - спектральный класс с десятичным подразделением, const - созвездие и обозначение; буква d означает, что звезда двойная и содержится в списке двойных звезд на стр. 43-47, буква v - наличие соседней звезды, что указано в списке близких между собой звезд на стр. 48.

Спектральный класс в основном зависит от температуры звезды, определяющей ее цвет. Это соотношение приблизительно таково:

Спектр	Показатель цвета, вел.	Цвет	Температура
B0	-0.3	Голубоватый	30000°K
A0	0.0	Белый	11000
F0	+0.3	Желтоватый	7600
G0	+0.6	Желтый	6000
K0	+1.0	Оранжевый	5100
M0	+1.6	Красный	3600

Переменные звезды. Некоторые звезды периодически или неправильно меняют свой блеск. Такие переменные звезды отмечены на картах особым значком - колечком (var) в тех случаях, когда звезда в максимуме блеска не слабее 6,5 величины и амплитуда его изменения превышает 0.3 величины. Список таких звезд приведен на стр. 43, в котором после координат α и δ указаны в графе max - min предельные величины в максимуме и минимуме блеска, далее, тип переменности, период в сутках и обозначение. Тип переменности указан буквами:

- C - цефеида,
- E - затменная,
- I - неправильная,
- M - долгопериодическая,
- N - новоподобная,
- S - полуправильная.

Двойные звезды. Значительная часть звезд - двойные, состоящие из двух, а иногда и больше, физически близких между собой звезд, совершающих орбитальное движение вокруг общего центра массы. В редких случаях среди двойных звезд встречаются оптические пары, лишь проектирующиеся на небесную сферу по общему направлению, но в действительности находящиеся на разных расстояниях от нас и далеко одна от другой. На наших картах отмечены особым образом (перечеркнуты) те звезды (dir), двойственность которых может быть замечена в небольшой телескоп с отверстием в 10-12 см. Список таких звезд приведен на стр. 43-47, в котором кроме координат α и δ дана суммарная величина Σ , величины обеих составляющих (mag), видимое угловое расстояние (dist) в секундах дуги и обозначение или созвездие (const). Периоды обращения большинства таких звезд исчисляются сотнями лет и поэтому расстояния меняются очень медленно. В редких случаях, когда имеется быстрое орбитальное движение, заметно изменяющее расстояние, такая пара отмечена буквой „o”.

Близкие звезды. К двойным звездам обычно относятся пары, угловые расстояния между которыми не превышают 40". Однако есть пары звезд, чаще всего оптические, со значительно большими расстояниями, но еще недостаточными для того, чтобы в масштабе карт пометить каждую в отдельности. Такие звезды на картах подчеркнуты и отнесены к разделу vic = vicinae - соседние. Их угловое расстояние находится в пределах 0'.7-10'. Список таких звезд приведен в таблице на стр. 48, где опять наряду с координатами обычно более яркой звезды пары, даны величины обеих звезд и угловое расстояние в минутах дуги между ними, а также обозначение и созвездие.

Звездные скопления и туманности. На картах особыми знаками помечены те из этих объектов, которые видны в небольшую трубу или светосильный бинокль и, в виде исключения, еще несколько таких, которые хотя трудно доступны малым инструментам, но представляют особый интерес и часто упоминаются в астрономической литературе. Отдельно показаны рассеянные (scm) и шаровые (glb) звездные скопления, туманности (neb), кроме планетарных (pln). Их список приведен на стр. 48, в котором указаны координаты середины объекта, его примерные угловые размеры (dim) в минутах дуги приближенная суммарная величина (mag), тип, именно

G - шаровое скопление,
 O - рассеянное скопление,
 N - неправильная туманность,
 P - планетарная,
 S - спиральная.

Обозначения указаны по каталогу Мессье - M, по Новому общему каталогу NGC или Индекс-каталогу IC. В последнем столбце указано созвездие.

Млечный Путь на картах изображен схематически, приблизительно растущими изохотами. Средняя линия Млечного Пути - галактический экватор, нанесен тонкой синей линией. Северный полюс Галактики принят согласно международному решению $\alpha = 12^h 49^m$, $\delta = +27^\circ 05'$ для равноденствия 1950.0.

Таблица прецессии. Для приведения экваториальных координат к другой эпохе равноденствия служит таблица на стр. 50, в которой даны изменения прямого восхождения и склонения в сто лет. Прецессия по α зависит от обеих координат и поэтому соответствующая таблица имеет два входа, причем аргументы α и δ нужно брать сверху и слева, либо снизу и справа; вековая прецессия по прямому восхождению получается тогда в минутах времени. Прецессия по склонению зависит только от α и таблица дает вековую прецессию по δ в минутах дуги.

ПРИМЕЧАНИЯ

- 1) Б. туманность Андромеды
- 2) Спиральная туманность в Треугольнике
- 3) Двойное скопление в Персее
- 4) Крабовидная туманность
- 5) Б. туманность Ориона
- 6) "Ясли" - Рагезере
- 7) Спиральная туманность в Б.Медведице
- 8) "Взрывающаяся" галактика
- 9) Спиральная туманность в Гончих Псах
- 10) "Тройная" туманность - Trifid
- 11) Туманность "Омега"
- 12) Кольцевая туманность в Лире
- 13) Туманность "Dumbbell"

ОГЛАВЛЕНИЕ

	Стр.
Объяснение к Атласу	3
Собственные имена звезд	5
Названия созвездий	6
Общий каталог звезд	7
Список переменных звезд	42
Список двойных звезд	43
Список близких между собой звезд	48
Список скоплений и туманностей	48
Таблица прецессии	50
Карты 1—20.	

Михайлов Александр Александрович
АТЛАС ЗВЕЗДНОГО НЕБА

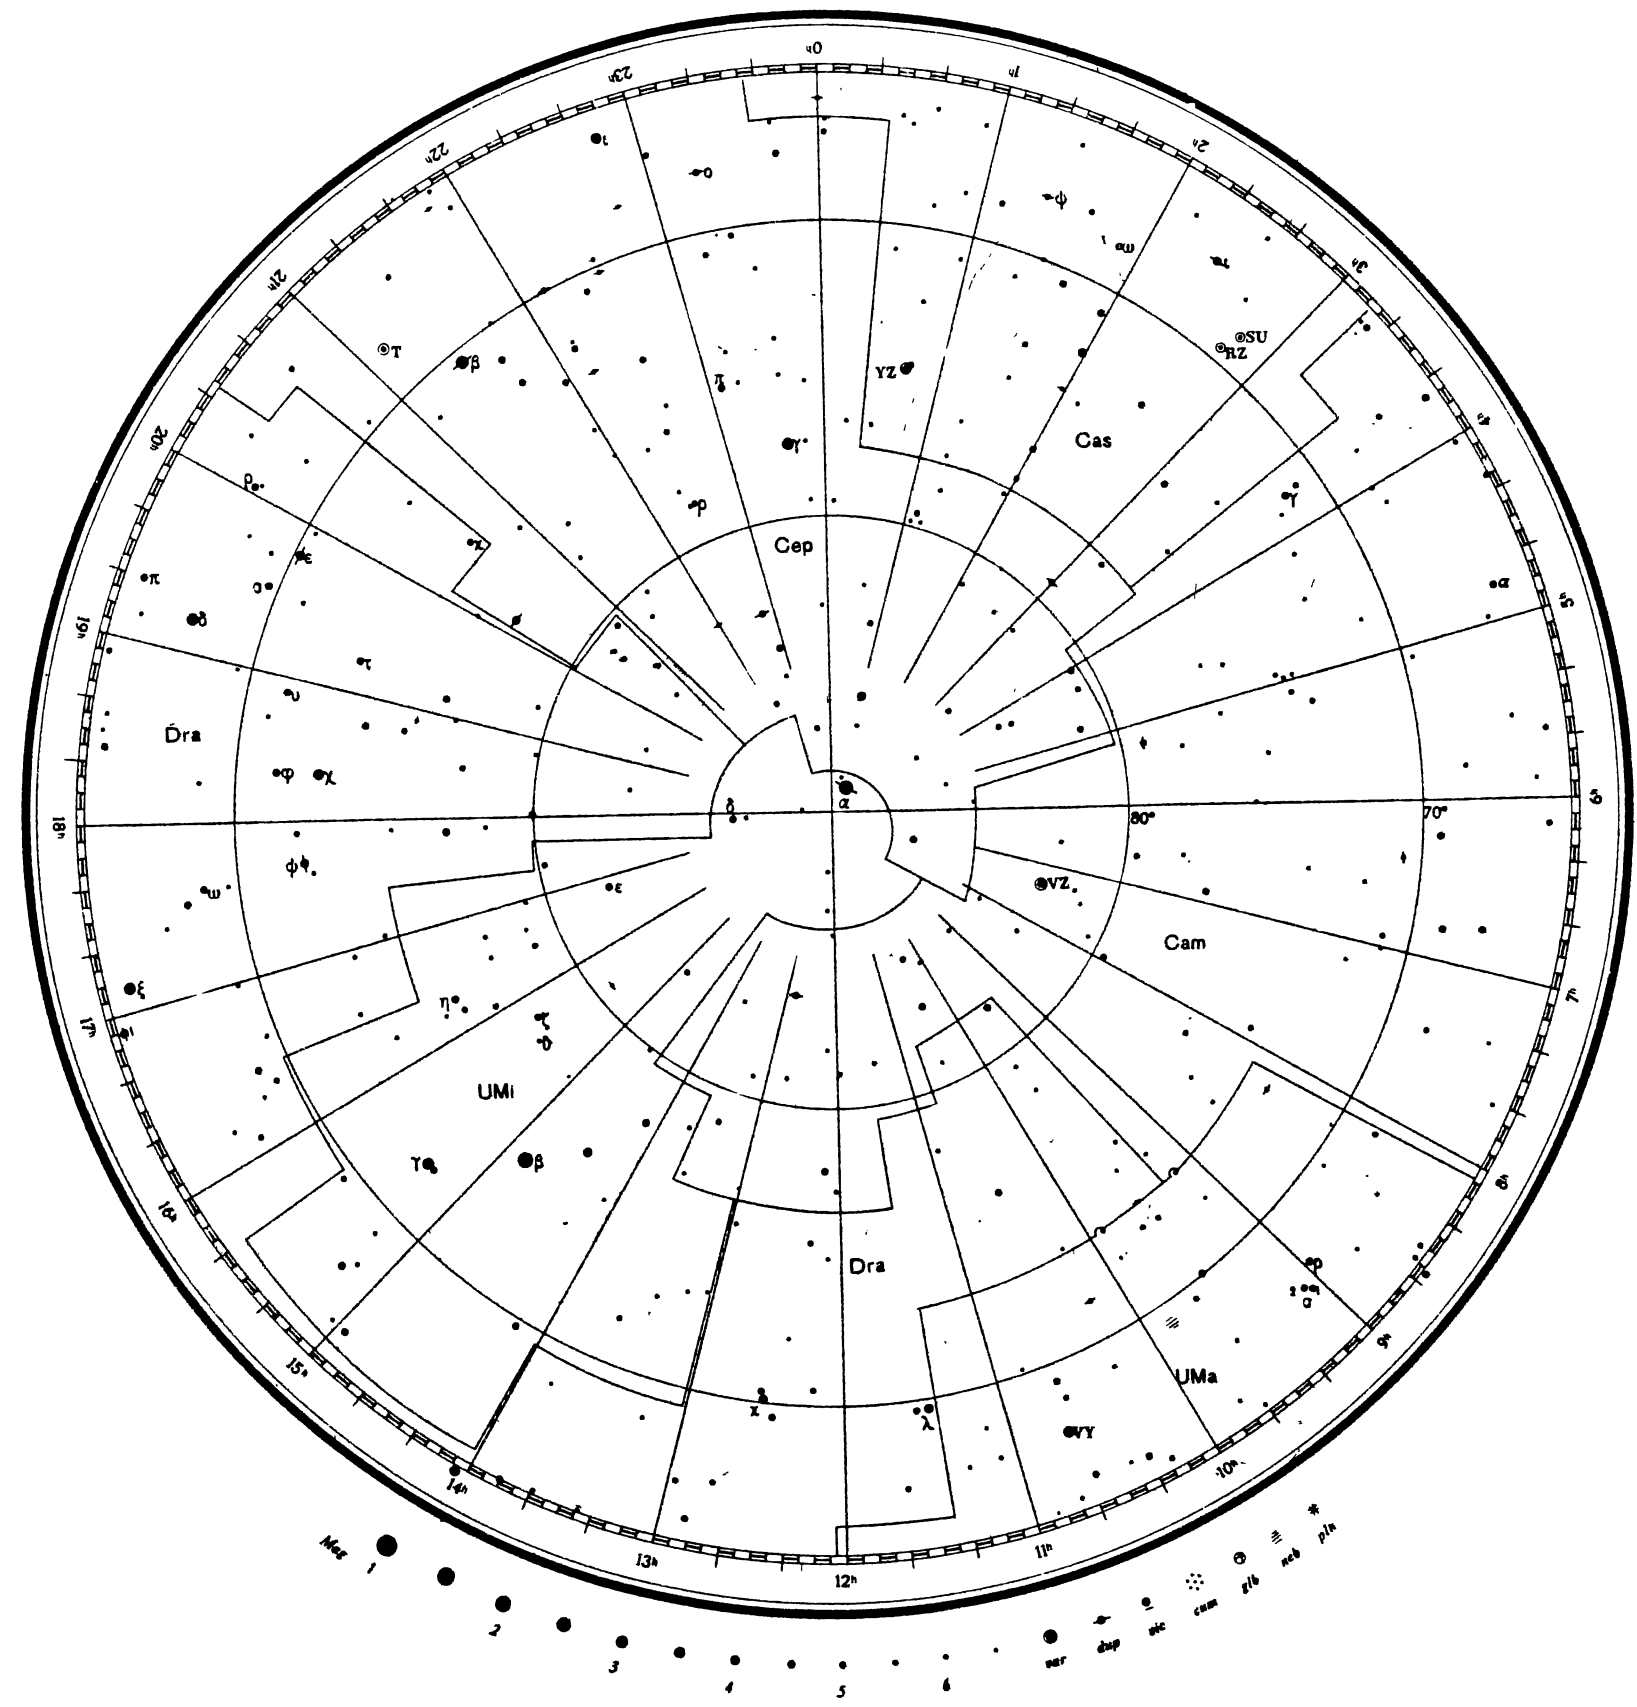

Объяснение и полный каталог
всех изображенных на картах звезд и объектов

Утверждено к печати
Главной астрономической обсерваторией АН СССР

Сдано в производство и подписано к печати 13/XI 1973 г.
Формат бумаги 70 x 108 1/8. Бумага № 1. Печ. л. 6 1/2 =
= 9.10 усл. печ. л. Уч.-изд. л. 13.80. Изд. № 4732.
Тип. зак. № 1371. М - 05965. Тираж 15 500.
Цена атласа с приложением брошюры 1 р. 80 к.

Ленинградское отделение издательства „Наука“, 199164, Ленинград,
Менделеевская линия, дом 1.
